

Curiosity ignored the cat: How exploration promotes context-dependent distractor suppression in visual search through real-world scenes

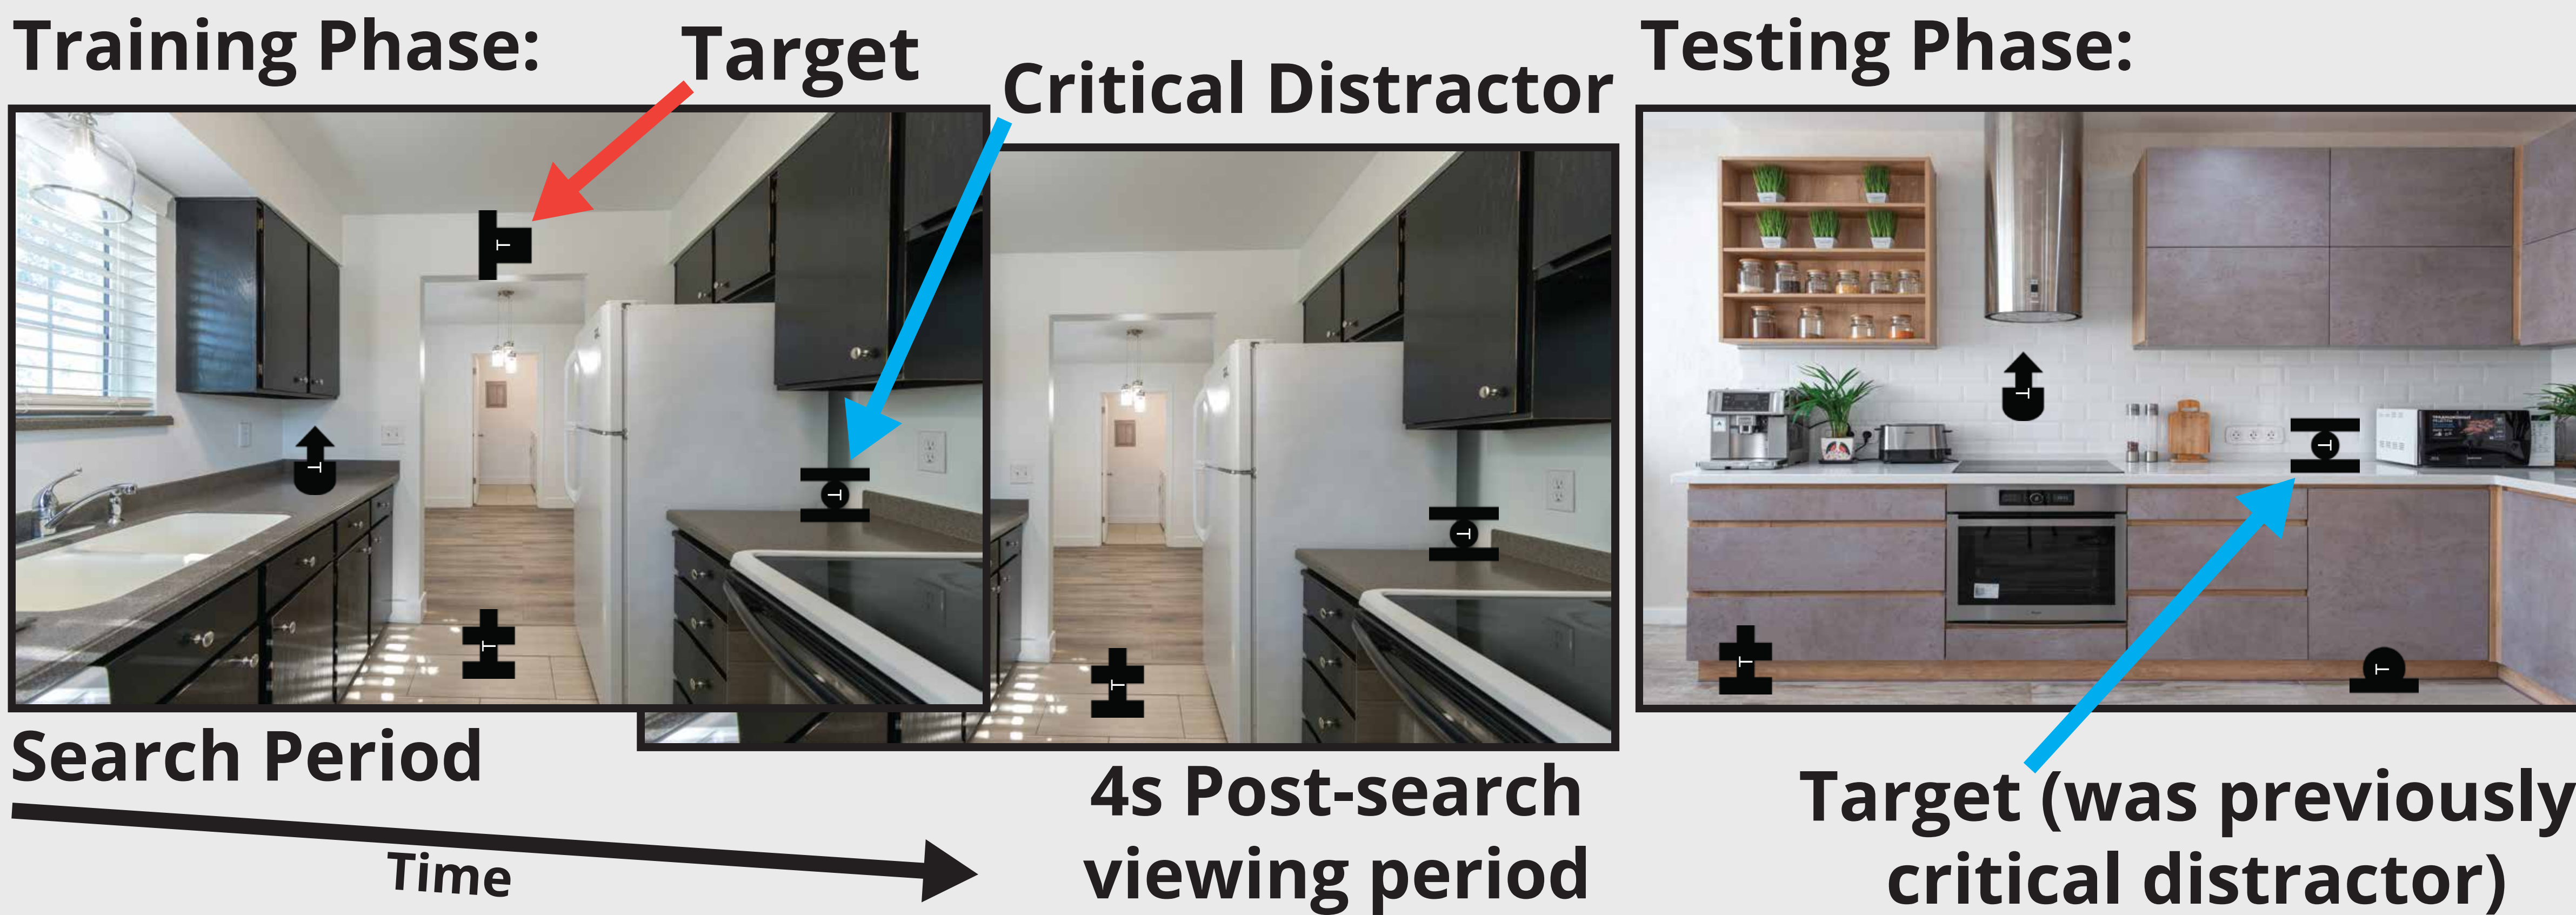

Justin L. Frandsen & Brian A. Anderson

Introduction

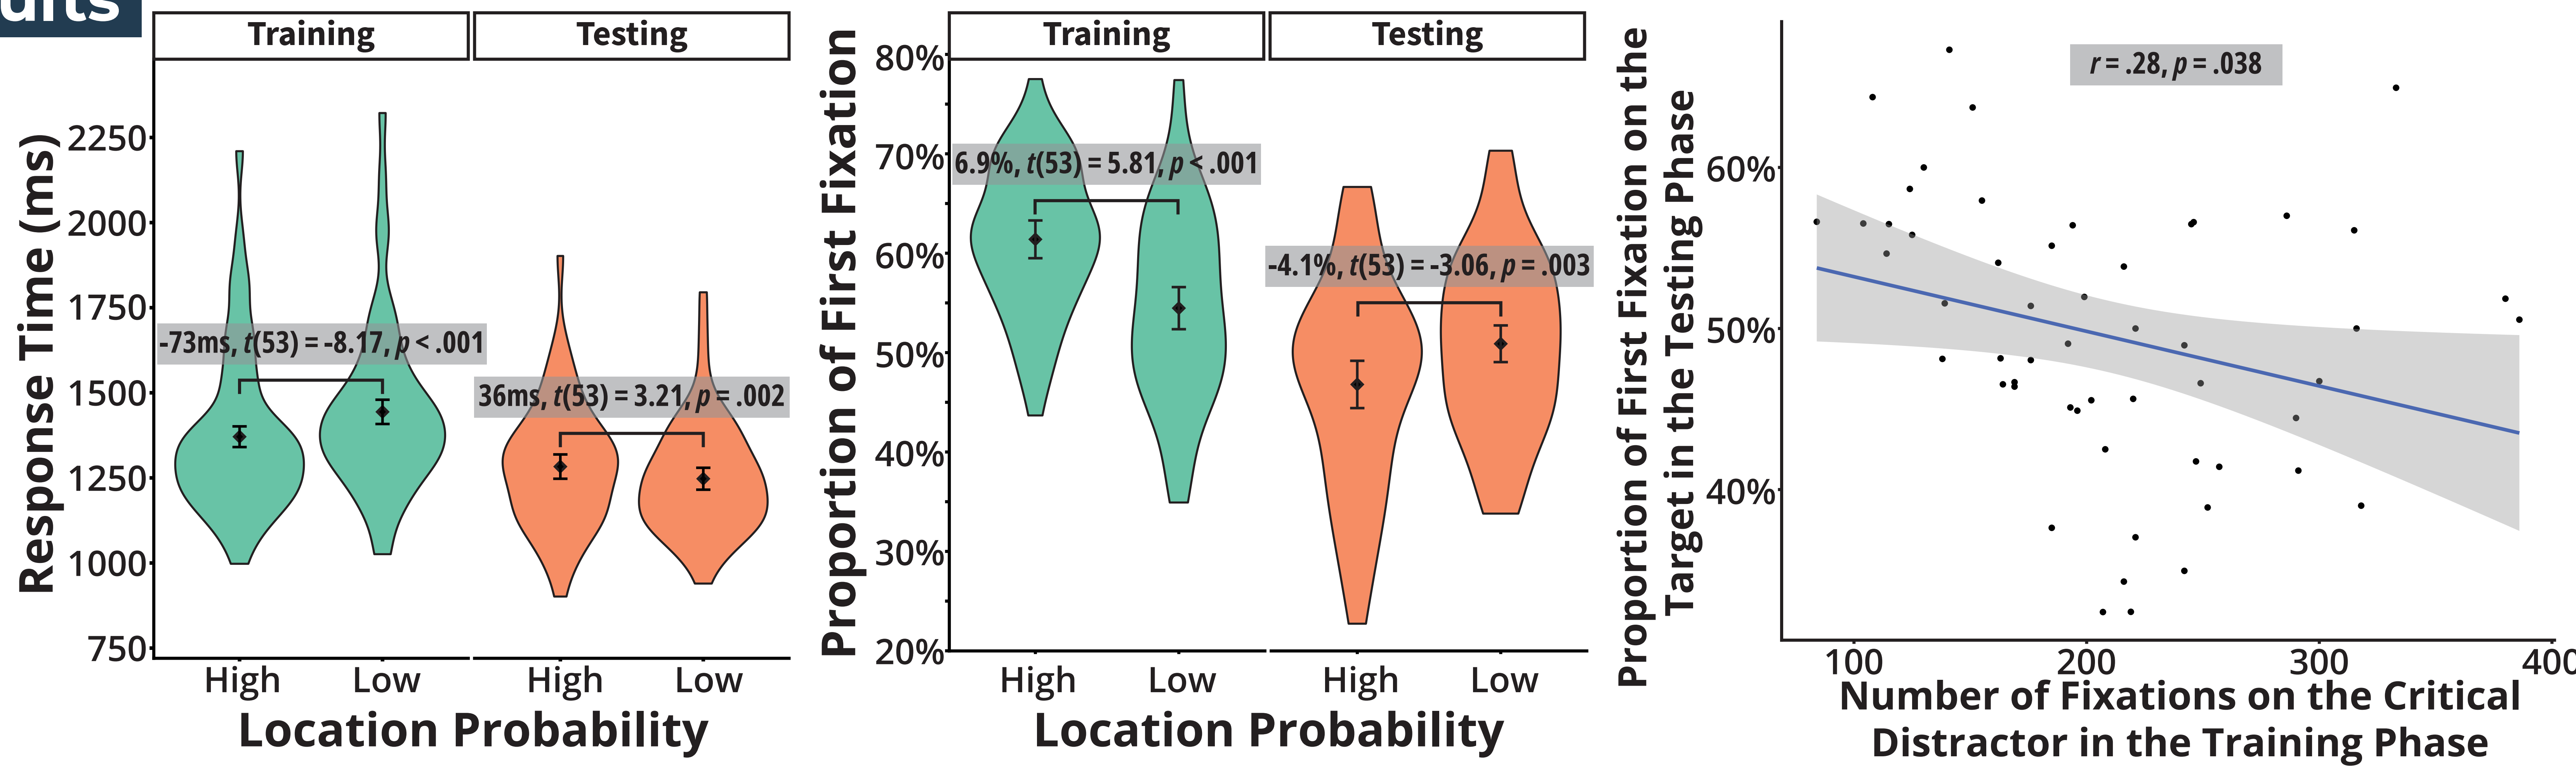

- Past work showed that **statistical regularities** of where **targets** occurred could guide search in **naturalistic scenes**¹.
 - **Statistical learning** often facilitates learning of **irrelevant distractor information**².
 - However, **fixating a distractor** during search for a different target **doesn't speed** subsequent search for said **distractor**^{3, 4}.
- Can statistical regularities of where a distractor occurs guide subsequent search?

Method

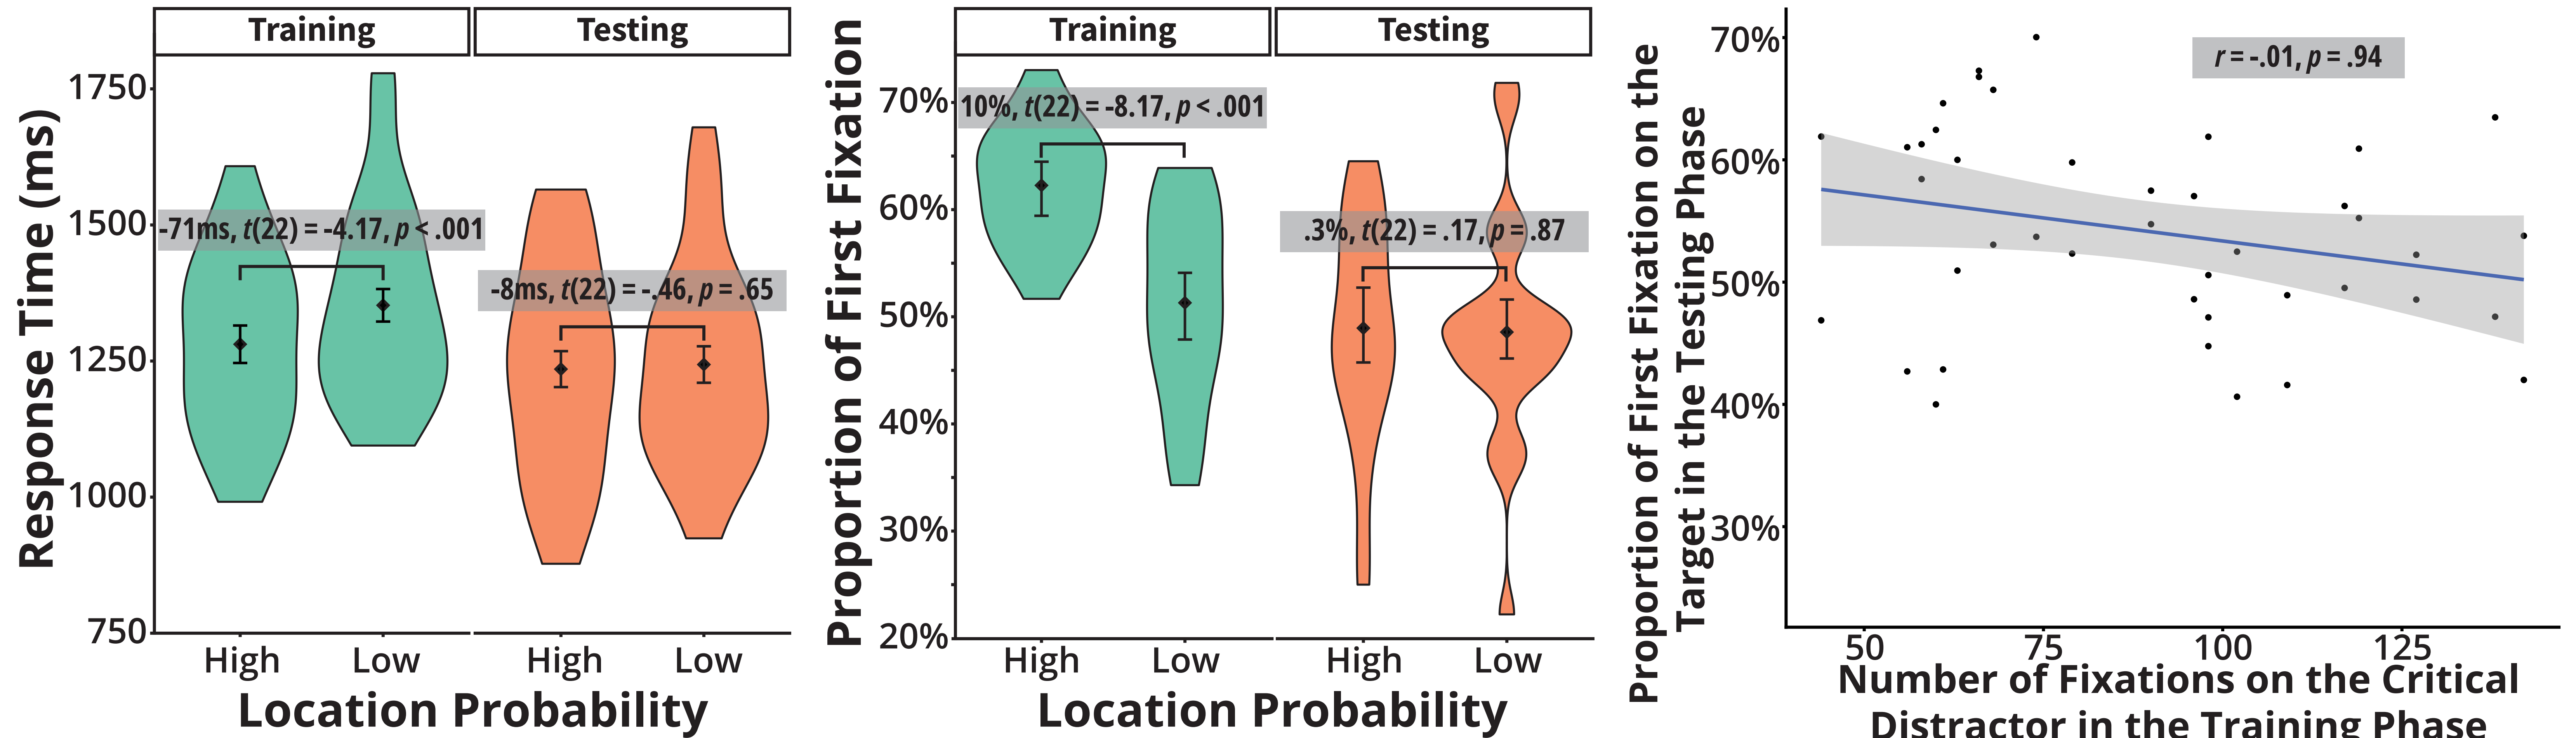

Results

Experiment 1

Experiment 2

Discussion

- Experiment 1 found that **statistical regularities of distractors** were learned in the training phase and **later suppressed** when searched for in the testing phase.
- In Experiment 2, when the **post-search viewing period was removed** this **learning went away**. This suggests that participants **can't learn** these regularities **during the task**.

People learn to suppress distractors in frequently encountered locations in scenes through post-search exploration.
